

Evaluation of a multi-model seasonal hydrological forecast prototype for the spring flood period in Sweden

By: Kean Foster,

Co-authors: Cintia Uvo, Jonas Olsson, Wei Yang, Johan Södling, Tomas Bosshard and Peter Berg

Hydropower was
the driving force

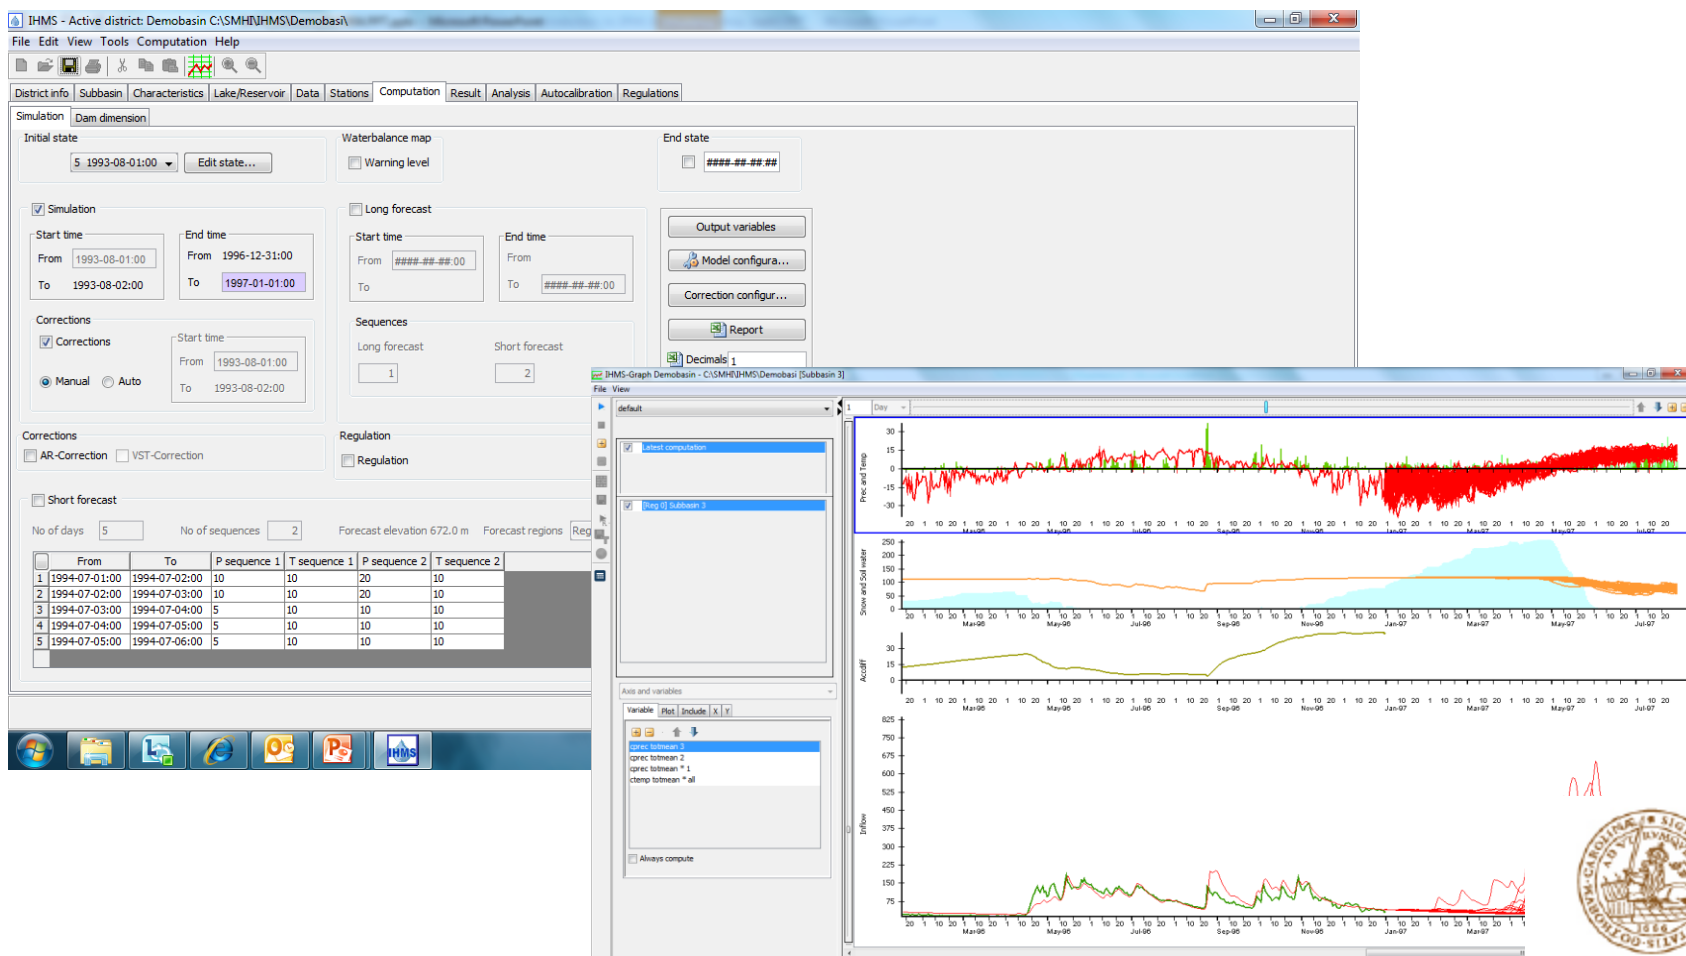

Background - Hydropower in Sweden

- **Sweden is the biggest hydropower producer in the EU and the 10th biggest worldwide (IEA 2012)**
- **Hydroelectric capacity :** **16 781 MW**
 - % of total installed capacity : 42.79%
 - % of total renewable capacity : 67.81%
- **Annual production (last 10 years) :** **73 TWh**
 - approx. 45% of the country's total consumed electricity

Climatologic ensemble: Limitations

- Climatologic ensemble → Seasonal forecast evolution follows the climatology of the driving data
- No notable improvement in performance over the last 25 years

Schematic of the Multi-model prototype

HBV

Forecast

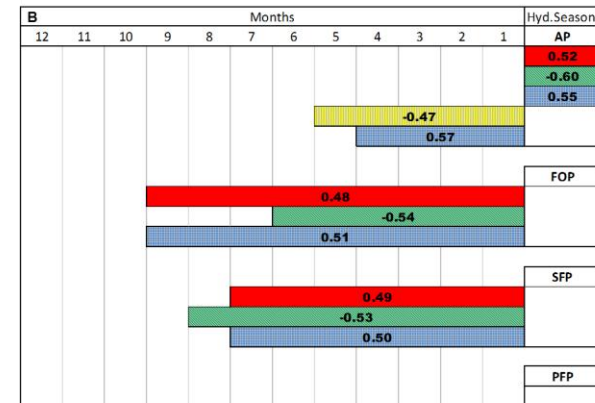

Reduced ensemble: TCI method

- Teleconnection Climate Indices
 - NAO
 - AO
 - SCAND

- Select all years with comparable TCI combinations

- Run HBV with reduced ensemble

Seasonal NWP based forecast:

NWP

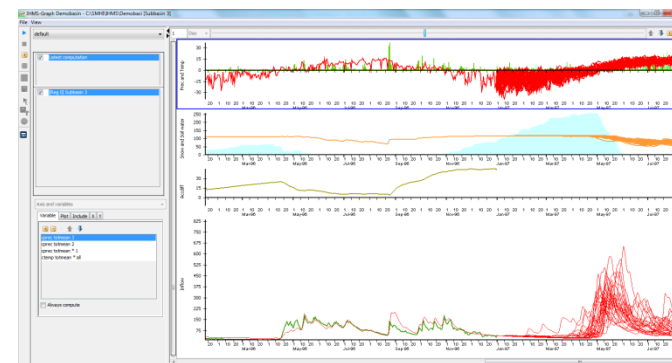

~100 km

HBV

Forecast

ECMWF forecasts in HBV: method

- ECMWF seasonal forecasts
 - 51 ensemble members
 - Daily P and T → Bias correction and remapping to HBV grid format
- Run HBV with ECMWF ensemble

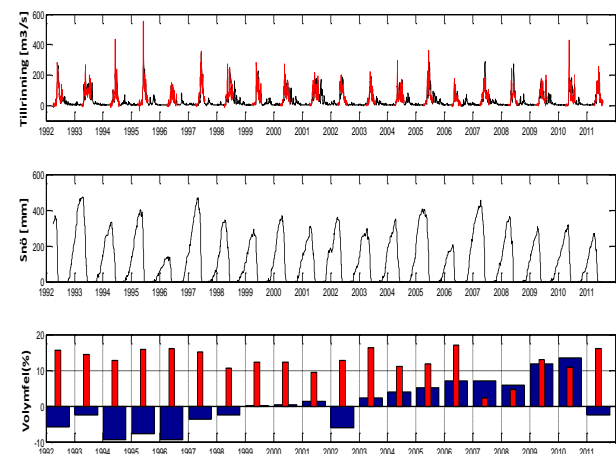

Statistical downscaling:

NWP

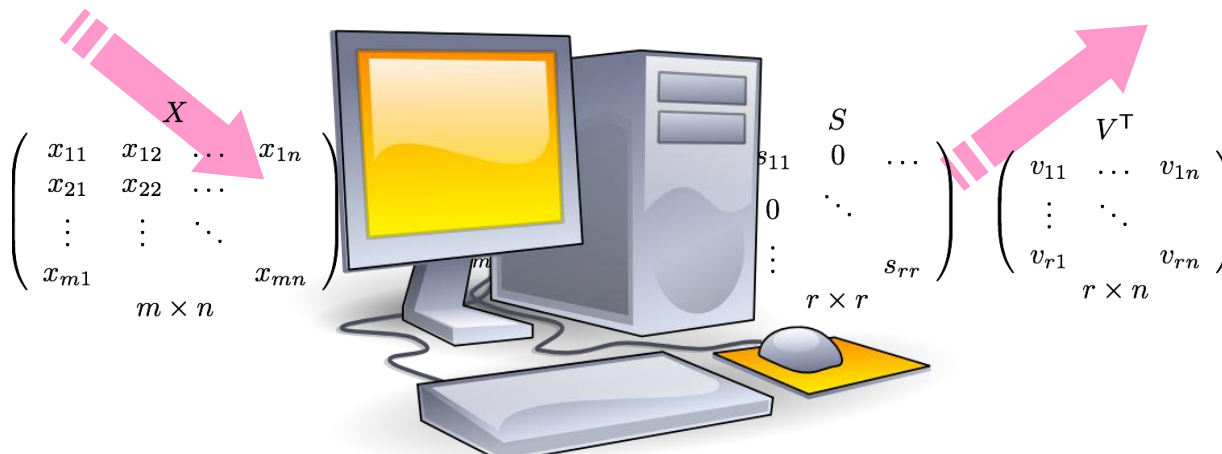

~100 km

Forecast

SVD

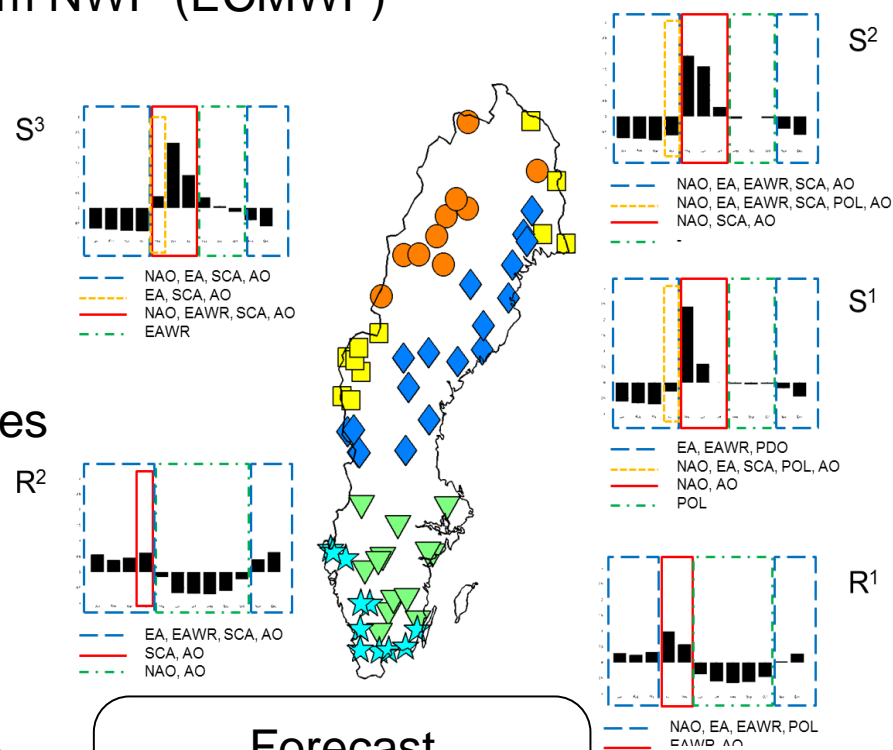

Statistical downscaling: method

- Atmospheric variables predictors from NWP (ECMWF)

- Pressure field variables
- Temperature/radiation variables
- Moisture variables

- Observed Seasonal discharge volumes

Conclusions

- Climatological spring flood forecasts are difficult to beat.
- For single basins and forecast dates, a reduction of the forecast error by up to 30%.
- The Multi-model shows more skill at forecasting anomalies and is able to reduce the forecasted volume error by 10% points on average.
